

Intro to Containers & Docker

- **Containers**
- Runtimes and Docker
- Why?
- Demo: Running a container
- Lab: Using Docker
- Review

Containers are just a process that's isolated from other processes on the same machine.

Bare Metal = Whole machine

VMs = OS and up

Containers = App and Dependencies

Back in the day, you had to put in a PO to get a server, which may take months, then someone had to rack it, install an os, all dependencies, and your app.

Then VMware and others made VMs popular, allowing folks to get whole "machines" faster and potentially smaller on existing hardware, make this process take weeks or minutes.

Containers get even more density since they don't have redundant OSes, and it only takes seconds to run a container. There is also no virtualization layer between the process and the OS, so no performance impact.

Features of the Linux Kernel

cGroups

Limit & Measure

- RAM usage
- cpu usage
- disk I/O
- network throughput
- etc

Namespaces

Isolate

- users
- NICs
- inter-process comms

chroot

FS Jail

- Changes apparent root directory for the process

Other

- Bind Mounts
- seccomp policies
- user and group permissions

There is no actual "container" construct on the machine. It's really just a process that has been isolated from other processes with these linux kernel features. Since an app is bundled with all of its dependencies, including system libraries, it can run on any Linux machine. It doesn't matter if the host is RHEL, Debian, Suse, etc.

Check out <https://ericchiang.github.io/post/containers-from-scratch/> to see how to create a container yourself 'by hand'

Tarball

Basic Root Linux FS

Dependencies + App

Container Metadata

```
/
/bin/
/dev/
/etc/
/home/
/usr/
/lib/python3.4/dist-packages/
/myapp/app.py
manifest.json
```

A container image is how we bundle our application and its dependencies, as well as specify how to run our application in metadata. Dependencies may include application runtime, system libraries, language libraries, etc. This is the filesystem that will be visible to the running application.

Sysdig docker usage report - 2018

8

Docker is a company that created a tool, also called docker, that makes it easy to package container images and run them. They are currently the most popular container runtime, others are slowly gaining traction, however.

<https://sysdig.com/blog/2018-docker-usage-report/>

Dockerfile Example

```
FROM ubuntu:18.04  
  
COPY . /app  
  
RUN pip install -r requirements.txt  
  
EXPOSE 8080  
  
CMD python /app/app.py
```

Building an image

```
$ docker build -t my-python-app .  
Sending build context to Docker daemon 3.072kB  
Step 1/5 : FROM ubuntu:18.04  
--> c8b8dc953  
Step 2/5 : COPY * /app/  
--> 277eb9bb17a5  
...  
Successfully built 2dba64288a74  
Successfully tagged my-python-app:latest
```

A container filesystem is just a tarball.

The FROM is the starting point for our image. It contains packages and files that come with the Ubuntu linux distro (in this case). We do not need to start from a linux distro, this is a convenience to have things like text editors, python, etc. It also means our image is going to be larger than necessary by containing files we do not need for our app to run, this can also have security implications.

Great talk around minimal container images:

<https://www.youtube.com/watch?v=gMpIdbcMHul>

Docker run command

Develop
Intelligence

1. Extracts the image
2. Creates linux namespace, chroots, etc
3. Runs the process

```
$ docker run my-python-app
```

```
$ docker ps
```

CONTAINER ID	IMAGE	COMMAND	CREATED	STATUS	PORTS	NAMES
2c4d58864a71	my-python-app	"python app.py"	2 hours ago	Up 2 hours	8081->80/tcp	eager_tesla

Isolated

Portable

?

Lightweight

Consistent

Isolating apps is nothing new, solaris had zones and folks have been building jails in linux for a long time. This was cumbersome and mechanisms to ensure a process had access to all its dependencies were not yet popular.

Isolated - no noisy neighbor, secure

Lightweight - fast startup time, minimal overhead

Portable - sharable, deploy the same way everywhere

Consistent - all dependencies included

Using Docker

- Different isolation mechanism (there is no Linux kernel)
- IIS and .NET applications
- Option of additional Hyper-V isolation
- Docker support, nascent Kubernetes support

Which exist inside a container image?

1. Application Binaries
2. Application Dependencies
3. Operating System
4. Linux Kernel

What are some benefits of containers?
